Parallelization
Salient Features of the Solver

What did we do

- Developed a solver to simulate flow which is:

  - based on grid-free vortex methods

  - able to handle 3D flows around arbitrarily shaped bodies

  - based on a generic and extensible design

  - completely parallelized

  - well tested

Introduction
Overview of the Design
Parallelization
Salient Features of the Solver

Modeling Flow using Vortex Methods

- Flow is modeled by a set of vortex particles

- Velocity field generated by these vortex particles simulates flow velocity

- These particles advect, stretch and diffuse according to Navier-Stokes equations

Introduction

Domain Decomposition

- Aim of particle distribution: Nearby particles in same processors, Far-off in different
- SFC curves: Particles sorted according to a position based key

Figure: Typical SFC curve

Figure: Particle distribution among processors obtained using SFC

Introduction
Overview of the Design
Parallelization
Salient Features of the Solver

Velocity Computation: Serial

- Velocity due to nearby particles: calculated directly
- Velocity due to far-off particles: calculated using an approximation known as pseudo particles
- Velocity calculation based on an oct-tree data structure

Introduction
Overview of the Design
Parallelization
Salient Features of the Solver

Velocity Computation: Parallel

- Local tree traversal

- Collective Communication

- Selective Communication

Introduction

Parallelization
Salient Features of the Solver

Generic Design

- General enough to handle various types of particles: pseudo particles, boundary blobs, stretching ghost particles, regular vortex blobs etc.

- Enables lot of code re-use: e.g. same `VelCalculator` is used by `Boundary`, `Advection` and `Stretching` Managers

- New algorithms can be easily added to existing framework

Introduction
Overview of the Design
Parallelization
Salient Features of the Solver

Importance of Using Python

Advantages

- Shorter development time
  - 3 months to develop a generalized parallel flow solver
- Shorter code-base
  - 4400 lines (including test modules)

Disadvantages

- Longer run time
  - planning to Cythonize this code for speed-up

Introduction
Overview of the Design
Parallelization
Salient Features of the Solver

Parallel Code

- Used `mpi4py` for all parallel implementations

- `mpi4py` closely follows all MPI-2 C++ bindings

- Used `qsub` for effective process management

- Issues with parallel debugging

Introduction
Overview of the Design
Parallelization
Salient Features of the Solver

Testing

- Extensive testing using Python's unittest module and nose

- 48 test functions to test 56 functions

- Almost every part of the code runs atleast once during these tests

- 1250 lines out of 4400 lines code-base are test modules

Introduction
Overview of the Design
Parallelization
Salient Features of the Solver

Future Work

- Improve parallelization scale-up

- Cythonize

- Solve some test cases involving boundaries

- Interpolate vorticity on grid points for flow visualization
